

# Topic 7.2: Revisiting Merge Sort

# Merge Sort - Now with Recursion!

- We looked at merging two sorted arrays when we discussed Searching and Sorting
- We looked at a little not-so-animated break down of this sort
- Let's actually take a look at the code now

# Quick recap of Merge Sort's concept

- What you already know:
  - We've seen the merging step (go back to the sorting videos for this)
  - We've seen how the algorithm would split data into smaller parts.
    - *theoretically*
- *What we're adding today: The full recursive implementation!*
  - *this is actually going to be really easy :)*

0	1	2	3	4	5	6	7
1	4	0	5	9	-2	3	21

# Why now? Why Recursion?

- Why Recursion?
  - What's the base case?

# Why now? Why Recursion?

- Why Recursion?
  - What's the base case?

- 1 element is always sorted!

# Why now? Why Recursion?

- Why Recursion?
  - What's the base case?

- 1 element is always sorted!
- How do we break down the problem?

# Why now? Why Recursion?

- Why Recursion?
  - What's the base case?

- 1 element is always sorted!
- How do we break down the problem?
  - How do we get to 1 element?

1	4	0	5	9	-2	3	21

# What did the call stack look like?

0	1	2	3	4	5	6	7
1	4	0	5	9	-2	3	21

# What did the call stack look like?

0	1	2	3	4	5	6	7
1	4	0	5	9	-2	3	21

# What did the call stack look like?

0	1	2	3	4	5	6	7
1	4	0	5	9	-2	3	21

split([1,4,0,5])

rightSplit = [1,4]  
leftSplit = [0,5]

split([1,4,0,5,9,-2,3,21])

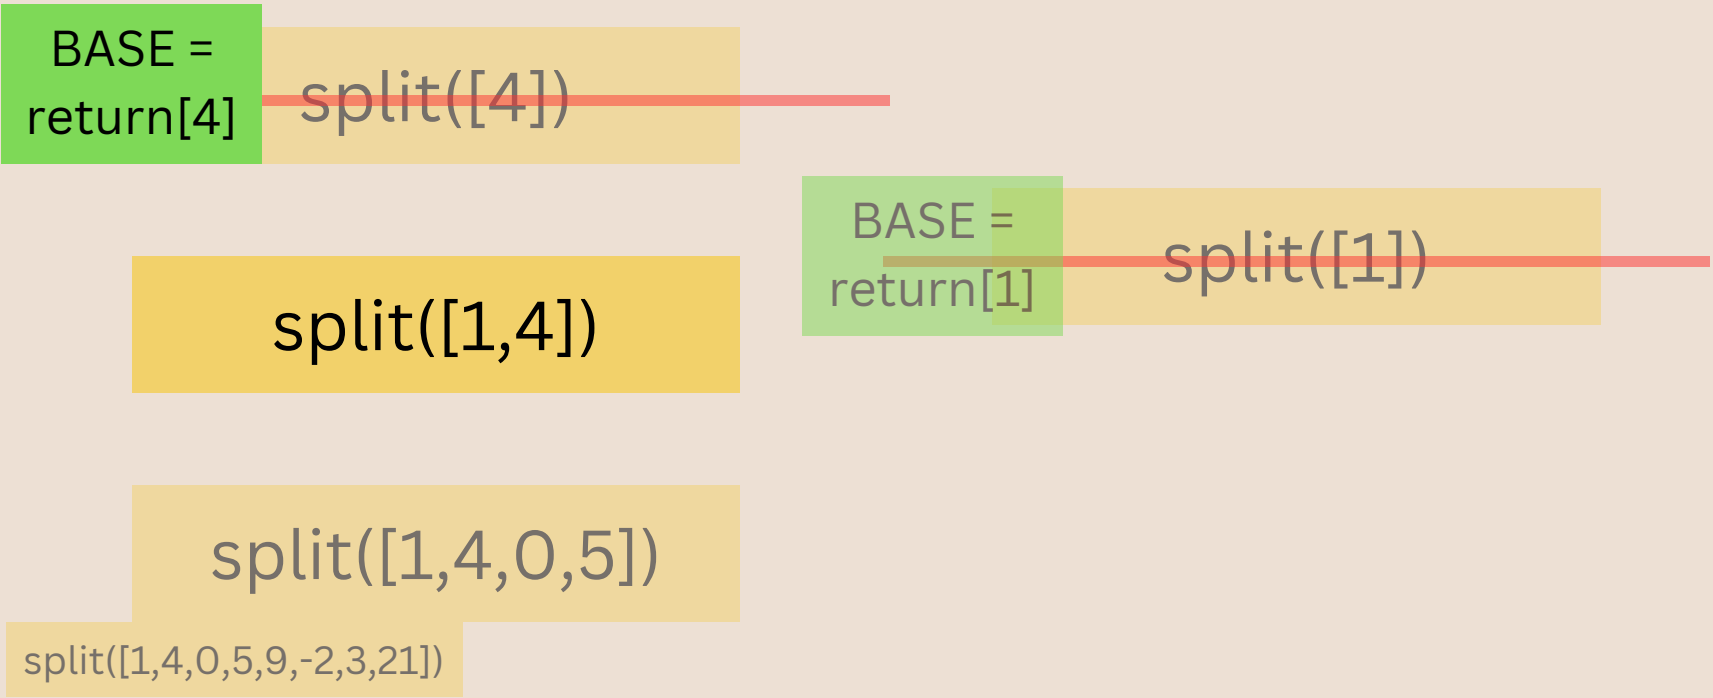

# What did the call stack look like?

0	1	2	3	4	5	6	7
1	4	0	5	9	-2	3	21

merge([1,4],[0,5])

split([1,4,0,5])

rightSplit = [1,4]  
leftSplit = [0,5]

split([1,4,0,5,9,-2,3,21])

# What did the call stack look like?

0	1	2	3	4	5	6	7
1	4	0	5	9	-2	3	21

# What did the call stack look like?

0	1	2	3	4	5	6	7
1	4	0	5	9	-2	3	21

`split([9,-2,3,21]`

`split([1,4,0,5,9,-2,3,21])`

`rightSplit =  
[0,1,4,5]`

## And then we do the other side...

# What did the call stack look like?

0	1	2	3	4	5	6	7
1	4	0	5	9	-2	3	21

```
merge([0,1,4,5],[-2,3,9,21])
```

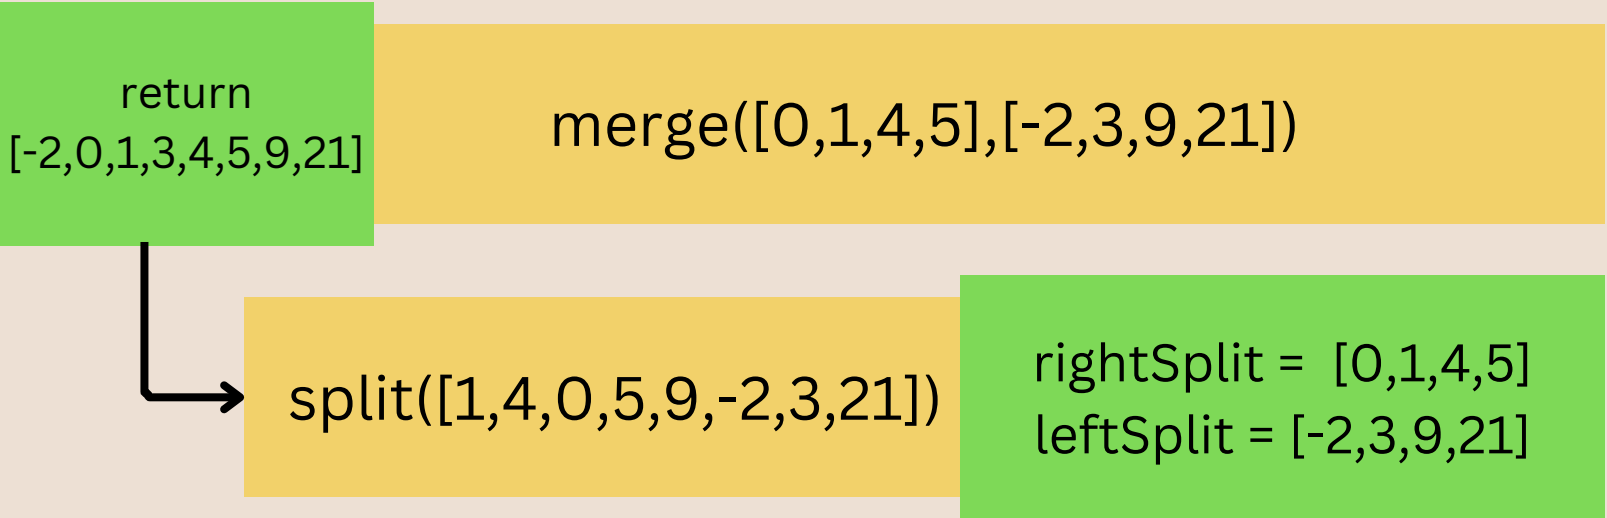

```
split([1,4,0,5,9,-2,3,21])
```

```
rightSplit = [0,1,4,5]  
leftSplit = [-2,3,9,21]
```

and then we merge it all together

# What did the call stack look like?

0	1	2	3	4	5	6	7
1	4	0	5	9	-2	3	21

aaannnnndddd....

# What did the call stack look like?

0	1	2	3	4	5	6	7
1	4	0	5	9	-2	3	21

TADA!

`split([1,4,0,5,9,-2,3,21])`

```
result = [-2,0,1,3,4,5,9,21]  
// this is returned to main or wherever
```

# PSEUDO CODE?

0	1	2	3	4	5	6	7
1	4	0	5	9	-2	3	21

```
function mergeSort(arr):  
    if length of arr is 1:  
        return arr  
    mid = find middle of arr  
    left = mergeSort(left half)  
    right = mergeSort(right half)  
    return merge(left, right)
```

This function is  
*recursive*

# So what sorts do we have now?

We know:

- insertion sort
- selection sort
- merge sort

But wait! There's more!!!

- We will see one more sort in just a few weeks when we talk about measuring how efficient our code really is

# Pause and Practice

0	1	2	3	4	5	6	7
1	4	0	5	9	-2	3	21

- Write the code! Implement Merge Sort and sort this array:
- How many recursive calls did your program make?
  - Count the number of times mergeSort is called.
- *Challenge*: Modify your code to count the total number of recursive calls automatically.
- How many comparisons occur during the merge step?
  - Count the number of element comparisons made only in the merging process.
- *Challenge*: Can you generalize this?
  - If an array has  $m$  elements, what is the maximum number of comparisons we might make during merging?
- How many comparisons would we make using Selection Sort instead?
  - Compare your result with Selection Sort's total comparisons.
